

Root Cause Analysis

Content Review & Appeal Accuracy · Fishbone (Ishikawa) Method

01 PROBLEM STATEMENT

Content Review accuracy was holding at 85.9% and Account Suspension accuracy at 88.0%, both below target. Specialist Appeal Rate was tracked alongside accuracy for a specific reason: low accuracy alone doesn't say whether specialists are making bad decisions or simply not trusting their own judgment enough to contest one. At 58.1%, Appeal Rate confirmed it was largely the latter, specialists weren't catching or contesting their own mismatches.

02 METHOD

A fishbone (Ishikawa) diagram was used to organize contributing factors into categories, rather than jumping to a single explanation. Each branch was validated against real appeal/confirmation data and Team Lead input before being treated as a genuine cause rather than a guess.

ROOT CAUSE ANALYSIS · FISHBONE (ISHIKAWA) DIAGRAM

Effect: Content Review accuracy 85.9% → 96.1%, Account Suspension 88.0% → 97.2%, Appeal Rate 58.1% → 87.5% after addressing the causes above.

03 PRIORITIZED ROOT CAUSES

CATEGORY	ROOT CAUSE	EVIDENCE
Tools & Data	No dashboard existed to track appeal / confirmation rate at the individual level	Confirmed as primary driver — addressed first
Visibility	Specialists only received performance visibility monthly — too infrequent to catch and appeal mismatches while they were still actionable	Confirmed as primary driver — addressed first
People	Low confidence appealing markdown decisions — specialists doubted their own read without data to back it up	Confirmed as primary driver — the reason Appeal Rate was tracked at all
Process	QC feedback loop to specialists was slow and manual	Secondary — partially addressed
Policy & Training	Policy updates inconsistently communicated; infrequent refreshers	Contributing, not primary — monitored

04 RESOLUTION

The Moderators Appeal/Confirmation Rate dashboard was built with the APAC CO manager to directly close the Tools & Visibility gaps, which in turn addressed the People root cause too. Specialists' low confidence wasn't a personality problem, it was that they had no data to back up a hunch that a markdown was wrong, and monthly reporting meant any pattern was long gone by the time they saw it. A Feishu Base automation was added to push a weekly moderator performance scorecard directly to Team Leads and specialists, replacing the monthly cadence so specialists could see their own mismatch pattern while it was still fresh enough to act on.

Giving specialists that evidence is what turned hesitation into action: appeal rate rose from 58.1% (W15) to 87.5% (W32), which in turn drove Content Review accuracy from 85.9% to 96.1% and Account Suspension accuracy from 88.0% to 97.2% over the same period.

Key takeaway: the accuracy gap wasn't primarily a skills problem: it was a visibility problem. Specialists needed to see their own pattern of errors to know what to appeal and what to learn from.
